# PROBLEM SET 5 Due back by Tuesday May 2.

Name: DI SANGRO MARIA VITTORIA

Id: 200211

## **Instructions:**

- Make sure you are working on your problem set as each problem set is different.
- The answers to the questions of this problem set are to be given exclusively in the answer sheet
- The answers sheet MUST be printed and not photocopied. Photocopies will not be accepted.
- Questions marked with the symbol & admit more than one correct answer
- Please fill the boxes in the answer sheet completely using a black pen as follows

Question 1: B C D E

- The answer sheet must not be creased or folded otherwise your problem set won't be graded.
- You can hand back your problem set at the END of class on May 2.

With a sample of 706 observations, we estimate the following model:

$$ln(hwage_i) = \beta_0 + \beta_1 age_i + \beta_2 age_i^2 + \beta_3 educ_i + \beta_4 yngkid_i + u_i$$

and obtain these results:

$$ln(hwage_i) = -1.00179_{0.41175} + 0.07121_{0.01941} \\ age_i - 0.00076_{age_i^2} + 0.07131_{0.01116} \\ duc_i + 0.09439yngkid_i \\ age_i - 0.00024_{0.01002} \\ age_i + 0.07131_{0.01116} \\ age_i - 0.09439yngkid_i \\ age_i - 0.00076_{0.00024} \\ age_i - 0.000$$

where *lhwage* is the logarithm of the hourly wage in euro, *age* is measured in years, *educ* is years of education and *yngkid* is a variable equal to 1 in case the person has a child younger than three years.

## **Question 1** What is the interpretation of $\beta_4$ ?

- A If a person has one small kid more, he/she earns about 0.095 more per hour with respect to someone who does not have small kids, ceteris paribus.
- B If a person has small kids (; 3 years old), he/she earns about 0.095 euros more per hour with respect to someone who does not have small kids, ceteris paribus.
- C If a person has one small kid more, he/she earns about 9.5% more per hour with respect to someone who does not have small kids, ceteris paribus.
- D If a person has small kids (; 3 years old), he/she earns about 9.5% more per hour with respect to someone who does not have small kids, ceteris paribus.

## **Question 2** What is the interpretation of $\beta_2$ ?

- A Increasing age by one year, the hourly wage decreases by 0.077% on average, ceteris paribus.
- B Increasing the square of age by one year, the hourly wage decreases by 0.00077 euros on average, ceteris paribus.
- C Increasing the square of age by one year, the hourly wage decreases by 0.077% on average, ceteris paribus.
- D By itself does not have a proper interpretation.

### **Question 3** What are we testing when we check whether $\beta_2$ is significant?

- A We check whether the logarithm of hourly wage depends positively on age.
- B We check whether the logarithm of hourly wage depends negatively on age.
- C We check whether the logarithm of hourly wage depends on age.
- D We check whether the logarithm of hourly wage depends linearly on age.

## Question 4 What is our null hypothesis when we test whether $\beta_1$ and $\beta_2$ are jointly significant?

- A We check whether the logarithm of hourly wage depends on age.
- B We check whether the logarithm of hourly wage is 0 when age is equal to 0.
- C We check whether the logarithm of hourly wage depends linearly on age.
- D We check whether the relationship between the logarithm of hourly wage and age is convex or concave.

- At about 56.3 years.
- B At about 46.7 years.
- C At about 93.3 years.
- D At about 0, but this makes no sense.

Question 6 Using a subset of the variables in the previous model, we would like to write a new one such that we obtain the elasticity of the hourly wage to education, and that, given in increase of one year in age, it returns a change in hourly wage in percent points. Choose the correct model among these:

- $\boxed{\mathbf{B}} \ ln(hwage_i) = \beta_0 + \beta_1 age_i + \beta_2 ln(educ_i) + u_i$
- $\boxed{C} ln(hwage_i) = \beta_0 + \beta_1 age + ln(\beta_2 educ_i) + u_i$
- $\boxed{E} ln(hwage_i) = \beta_0 + \beta_1 ln(age_i) + \beta_2 educ_i + u_i$

 $\mathbf{2}$ 

Let us define with Y the amount of cholesterol in mlg in the blood and with Med a dummy variable which takes the value of 1 for medication B and 0 for medication A, where A and B are two different medications that lower cholesterol. Female is a dummy variable which takes the value of 1 for females and 0 otherwise.

Consider the following regression:

$$Y = \beta_0 + \beta_1 \times med + \beta_2 \times female + \beta_3 \times med \times female + u.$$

Question 7 What is the effect of using medication B with respect to no medication for men?

- A  $\beta_1$ - $\beta_0$
- $\beta_1$
- $\boxed{C}$   $\beta_0 + \beta_1$
- D None of the others.
- $\boxed{\mathrm{E}} \beta_0$

**Question 8** Suppose you use this model:  $Y = \beta_0 + \beta_1 \times med + \beta_2 \times female + u$  What would be the underlying assumption in this case?

- A Medication A and B do not operate differently between females and males.
- B Males and females choose to take the same medication (either A or B).
- C Medication A and B may operate differently between females and males.
- D None of the others.
- |E| There are no gender differences in the average cholesterol level.

#### Question 3

These data are taken from the Medical Expenditure Panel Survey survey conducted in 1996. These data were provided by Professor Harvey Rosen of Princeton University and were used in his paper with Craig Perry "The Self-Employed Are Less Likely Than Wage-Earners to Have Health Insurance. So What?" in Douglas Holtz-Eakin and Harvey S. Rosen, eds., Entrepeneurship and Public Po licy, MIT Press 2004.

Among the variables in the dataset, ins is a dummy equal to one if the interviewee has the insurance; selfemp is equal to one if the interviewee is a self-employed workers; gender is equal to one if the in dividual is a male; married is one if the individual is married; health is one if the individual reports to be in good health; educ is 0 if the person has no education, 1 if he/she achieved middle school diploma, 2 for the high school diploma, 3 for the bachelor degree, 4 for the master degree and 5 for the PhD; age is in years and age2 is the square of age.

We estimate two models:

$$Pr(ins = 1|X) = \beta_0 + \beta_1 \times selfemp + \beta_2 \times married + \beta_3 \times gender + \beta_4 \times health + \beta_5 \times gender * health + \beta_6 \times educ + \beta_7 \times age + \beta_8 \times age^2$$

#### Coefficients:

|               | Estimate S | td. Error t | value  | Pr(> t ) |
|---------------|------------|-------------|--------|----------|
| (Intercept)   | 0.2974634  | 0.0580248   | 5.13   | 0.000003 |
| selfemp       | -0.1742361 | 0.0141740   | -12.29 | < 2e-16  |
| married       | 0.1181062  | 0.0094187   | 12.54  | < 2e-16  |
| gender        | -0.0232270 | 0.0343575   | -0.68  | 0.49903  |
| health        | 0.0744310  | 0.0247243   | 3.01   | 0.00262  |
| genderxhealth | -0.0206248 | 0.0353131   | -0.58  | 0.55920  |
| educ          | 0.0529807  | 0.0029210   | 18.14  | < 2e-16  |
| age           | 0.0105315  | 0.0027482   | 3.83   | 0.00013  |
| age2          | -0.0000788 | 0.0000333   | -2.37  | 0.01796  |
|               |            |             |        |          |

Heteroskadasticity robust standard errors used

$$Pr(ins = 1|X) = \Phi(\beta_0 + \beta_1 \times selfemp + \beta_2 \times married + \beta_3 \times gender + \beta_4 \times health + \beta_5 \times gender * health + \beta_6 \times educ + \beta_7 \times age + \beta_8 \times age^2)$$
 (II)

#### Coefficients:

|               | Estimate  | Std. Error | z value | Pr(> z ) |
|---------------|-----------|------------|---------|----------|
| (Intercept)   | -0.844932 | 0.195991   | -4.31   | 0.000016 |
| selfemp       | -0.651923 | 0.046842   | -13.92  | < 2e-16  |
| married       | 0.455241  | 0.034845   | 13.06   | < 2e-16  |
| gender        | -0.040238 | 0.111653   | -0.36   | 0.71856  |
| health        | 0.300503  | 0.082988   | 3.62    | 0.00029  |
| genderxhealth | -0.124880 | 0.116613   | -1.07   | 0.28422  |
| education     | 0.226139  | 0.012852   | 17.60   | < 2e-16  |
| age           | 0.029150  | 0.009899   | 2.94    | 0.00323  |
| age2          | -0.000162 | 0.000126   | -1.29   | 0.19821  |
|               |           |            |         |          |

## **Question 9** What is the interretation of $\beta_6$ in model (I)?

- A Increasing years of education by one, makes the individual 5.3% more likely to have an insurance, holding all other things constant.
- B Increasing years of education by one, on average, makes the individual 5.3% more likely to have an insurance, *ceteris paribus*.
- C It does not have a proper interpretation.
- D Increasing a person's education level by one, on average, makes he/she 5.3% more likely to have an insurance, *ceteris paribus*.

## **Question 10** What is the interretation of $\beta_2$ in model (I)?

- A On average, married individuals are 11.8% more likely than others to have an insurance, controlling for all other factors.
- B On average, married individuals are 11.8% less likely than others to have an insurance, controlling for all other factors.
- C On average, increasing married by one increases the probability to have an insurance of 11.8%, ceteris paribus.
- D It does not have a proper interpretation.

Question 11 Does increasing level of education have a significant impact on the probability to buy an insurance at 5% level under model (II)?

- $\boxed{\mathbf{A}}$  No, since the coefficient  $\beta_6$  is not significant.
- B Yes, since the model includes the variable "educ".
- C It depends on the values of all other covariates.
- $\boxed{\mathrm{D}}$  Yes, since the coefficient  $\beta_6$  is significant.

Question 12 Does increasing level of education have a significant impact on the probability to buy an insurance at 5% level under model (I)?

- $\boxed{\mathbf{A}}$  No, since the coefficient  $\beta_6$  is not significant.
- B It depends on the values of all other covariates.
- C Yes, since the model includes the variable "educ".
- $\boxed{\mathrm{D}}$  Yes, since the coefficient  $\beta_6$  is significant.

Question 13 4 Under model (I), which of the following statements are true?

- A On average, self employed people are less likely to have an insurance, controlling for all other factors.
- B Statistically speaking, having a good health has the same impact on the probability of having an insurance for men and women.
- C The probability of having an insurance is linked to age in a linear fashion.
- D The older an individual grows, the higher the probability of having an insurance.
- E None of these answers are correct.

Question 14 . Under model (II), which of the following statements are true?

- A On average, self employment has a negative effect on the probability of having an insurance, ceteris paribus.
- B We cannot interpret directly the estimated coefficients in terms of magnitude.
- The probability of having an insurance for a married person is, on average, 45.5% higher than for other people, *ceteris paribus*.
- D We cannot possibly know whether education level has an effect on the probability of having an insurance.
- E None of these answers are correct.

**Question 15** In model (I) we used heteroskedastic-robust standard errors. Could have we used homoskedastic standard errors instead?

- A Only if we knew that the errors were in facts homoskedastic.
- B No, because homoskedasticity is not possible when the dependent variable is a dummy.
- C No, because homoskedasticity rarely occurs in nature.
- D No, because the errors are very likely to autocorrelated.

**Question 16** What is the estimated probability that a 24 years old non-educated non-self-employed single female who is not in good health and with middle school diploma will buy insurance coverage?

- A Approximately 0.5.
- B Less than 5%.
- C I cannot say because the model is nonlinear.
- D More than 95%.
